Reflections

You used custom properties to define a small set of design tokens in your starter stylesheet. Imagine a teammate joins your project six months from now and needs to add a dark mode. Explain how the token structure you set up would help or hinder that effort, and what you would change:

The token structure allows to minimize the time spent in adjusting and adding new properties because it acts similarly to a "control panel" for styles. Instead of searching through line by line of code the teammate will only need to change the values in one place. I would make sure all styles are a custom property and I would add a font-size token for headings and text.

Look at the starter CSS you added to your portfolio. Identify one value that is still hard coded (not using a custom property) that probably should be a token. Explain why extracting it would matter in a larger project:

The "line-height: 1.6;" line is still hard coded. If we wanted to change this property, we would have to find this specific line and change it manually. Large projects contain lots of files and trying to find this line would consume valuable time.

Browse one professional website you admire and open DevTools. Do they use custom properties? Describe what you found and one thing you would do differently based on what you learned this week:

I browsed the byui.edu website and noticed they are using custom properties particularly to their color palette. Something I noticed is that they have two variable names pointing to the exact same hexcode. This increases the risk of errors and would create confusion for teammates. I would define each color once.
